

GENERIC ACTIVATION AND REGISTRATION FRAMEWORK FOR WIRELESS
DEVICES

ABSTRACT

5

A system and a method are provided for managing network
activation with a carrier and registration with a service
provider. In one example, the method determines a network
activation status. If the network is not activated, a utility
10 is used to perform the activation. Further, the status of
registration with a provider is determined. If not
registered, a request is sent to a server of the service
provider for a registration file configured to gather user
registration information. The registration file is then
15 received from the server. The registration file is executed
on the personal computer. Data gathered by the registration
file is then returned to the service provider's server to
complete the registration procedures.
